

Clinical UM Guideline

Subject: Air Conduction Hearing Aids
Guideline #: CG-DME-37
Status: Reviewed

Publish Date: 12/16/2020
Last Review Date: 11/05/2020

Description

This document addresses the use of air conduction hearing aids in the treatment of individuals with hearing loss.

Note: Please see the following documents related to other treatments and devices for the treatment of hearing loss:

- CG-SURG-81 Cochlear Implants and Auditory Brainstem Implants
- CG-SURG-82 Bone-Anchored and Bone Conduction Hearing Aids
- SURG.00084 Implantable Middle Ear Hearing Aids

Note: Benefit language supersedes this document. Hearing aids are not a covered benefit under all member contracts/certificates. Please see the text in the footnote of this document regarding Federal and State mandates and applicable benefit plan contract language, as contract terms, conditions and limitations of coverage within these documents may specifically address the topic of hearing aids.

Clinical Indications

Medically Necessary:

Air conduction hearing aid devices are considered **medically necessary** for the treatment of hearing loss when **ALL** of the following criteria are met (A and B):

- A. The hearing loss is due to one of the following etiologies:
1. Sensorineural hearing loss; **or**
 2. Mixed hearing loss; **or**
 3. Conductive hearing loss which has been:
 - a. unresponsive to medical interventions; **and**
 - b. unresponsive to surgical interventions or not amenable to surgical correction; **and**
- B. The degree of hearing loss is confirmed by audiometry or other age-appropriate testing to be greater than or equal to 26 decibels (dB).

Binaural air conduction hearing aids are considered **medically necessary** when **BOTH** of the following criteria are met (A and B):

- A. Both ears meet the criteria listed above in A and B; **and**
- B. Binaural testing shows improved speech recognition using bilateral devices.

Air conduction hearing aid devices with advanced technology models and features (for example, in-the-ear and in-the-ear-canal models with digital signal processing, directional microphones, multiple channels/memories) are considered **medically necessary** when the technology enhancement is needed to improve the hearing quality for the wearer.

This Clinical UM Guideline is intended to provide assistance in interpreting Healthy Blue's standard Medicaid benefit plan. When evaluating insurance coverage for the provision of medical care, federal, state and/or contractual requirements must be referenced, since these may limit or differ from the standard benefit plan. In the event of a conflict, the federal, state and/or contractual requirements for the applicable benefit plan coverage will govern. Healthy Blue reserves the right to modify its Policies and Guidelines as necessary and in accordance with legal and contractual requirements. This Clinical UM Guideline is provided for informational purposes. It does not constitute medical advice. Healthy Blue may also use tools and criteria developed by third parties, to assist us in administering health benefits. Healthy Blue's Policies and Guidelines are intended to be used in accordance with the independent professional medical judgment of a qualified health care provider and do not constitute the practice of medicine or medical advice.

No part of this publication may be reproduced, stored in a retrieval system or transmitted, in any form or by any means, electronic, mechanical, photocopying, or otherwise, without permission from the health plan.

Air Conduction Hearing Aids

Replacement of an air conduction hearing aid device that is out of warranty and no longer functioning adequately to support activities of daily living is considered **medically necessary** when the device is malfunctioning and cannot be refurbished or repaired sufficiently to resume its original functionality.

Not Medically Necessary:

Air conduction hearing aid devices are considered **not medically necessary** when the above criteria are not met.

Air conduction hearing aid devices with advanced technology models and feature enhancements (for example, in-the-ear and in-the-ear-canal models with digital signal processing, directional microphones, multiple channels/memories) are considered **not medically necessary** when provided solely for the convenience of the wearer or to improve his/her cosmetic appearance.

Replacement of a currently functional air conduction hearing aid device that is still under warranty for the sole purpose of obtaining a device with updated technology, (commonly referred to as an "upgrade"), is considered **not medically necessary** unless the new updated device will provide a significant functional advantage over the device that was originally issued.

Coding

The following codes for treatments and procedures applicable to this document are included below for informational purposes. Inclusion or exclusion of a procedure, diagnosis or device code(s) does not constitute or imply member coverage or provider reimbursement policy. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

When services may be Medically Necessary when criteria are met:

HCPCS

V5030	Hearing aid, monaural, body worn, air conduction
V5050	Hearing aid, monaural, in the ear
V5060	Hearing aid, monaural, behind the ear
V5070	Glasses, air conduction
V5100	Hearing aid, bilateral, body worn
V5120	Binaural, body
V5130	Binaural, in the ear
V5140	Binaural, behind the ear
V5150	Binaural, glasses
V5242	Hearing aid, analog, monaural, CIC (completely in ear canal)
V5243	Hearing aid, analog, monaural, ITC (in the canal)
V5244	Hearing aid, digitally programmable analog, monaural, CIC
V5245	Hearing aid, digitally programmable, analog, monaural, ITC
V5246	Hearing aid, digitally programmable, analog, monaural, ITE (in the ear)
V5247	Hearing aid, digitally programmable, analog, monaural, BTE (behind the ear)
V5248	Hearing aid, analog, binaural, CIC

This Clinical UM Guideline is intended to provide assistance in interpreting Healthy Blue's standard Medicaid benefit plan. When evaluating insurance coverage for the provision of medical care, federal, state and/or contractual requirements must be referenced, since these may limit or differ from the standard benefit plan. In the event of a conflict, the federal, state and/or contractual requirements for the applicable benefit plan coverage will govern. Healthy Blue reserves the right to modify its Policies and Guidelines as necessary and in accordance with legal and contractual requirements. This Clinical UM Guideline is provided for informational purposes. It does not constitute medical advice. Healthy Blue may also use tools and criteria developed by third parties, to assist us in administering health benefits. Healthy Blue's Policies and Guidelines are intended to be used in accordance with the independent professional medical judgment of a qualified health care provider and do not constitute the practice of medicine or medical advice.

Air Conduction Hearing Aids

V5249	Hearing aid, analog, binaural, ITC
V5250	Hearing aid, digitally programmable analog, binaural, CIC
V5251	Hearing aid, digitally programmable analog, binaural, ITC
V5252	Hearing aid, digitally programmable, binaural, ITE
V5253	Hearing aid, digitally programmable, binaural, BTE
V5254	Hearing aid, digital, monaural, CIC
V5255	Hearing aid, digital, monaural, ITC
V5256	Hearing aid, digital, monaural, ITE
V5257	Hearing aid, digital, monaural, BTE
V5258	Hearing aid, digital, binaural, CIC
V5259	Hearing aid, digital, binaural, ITC
V5260	Hearing aid, digital, binaural, ITE
V5261	Hearing aid, digital, binaural, BTE
V5262	Hearing aid, disposable, any type, monaural
V5263	Hearing aid, disposable, any type, binaural

ICD-10 Diagnosis

All diagnoses

When services are Not Medically Necessary:

For the procedure codes listed above when criteria are not met or for situations designated in the Clinical Indications section as not medically necessary.

Discussion/General Information

Hearing aids are described by the U.S. Food and Drug Administration (FDA) as, "Any wearable instrument or device designed for, offered for the purpose of, or represented as aiding persons with or compensation for, impaired hearing" (FDA, 2001). Air conduction hearing aids are considered Class I devices by the FDA due to simplicity of design and minimal potential for harm to the user.

Externally worn air conduction hearing aid devices, which are also referred to as acoustic hearing aids, are widely accepted for use by individuals with mild to profound sensorineural hearing loss. Hearing loss can be tested by a variety of different modalities but the most common and reliable method is pure-tone audiometry, which is then rated on a scale based on the threshold of hearing ability. Severe to profound sensorineural hearing loss is defined by the American Academy of Otolaryngology-Head and Neck Surgery Foundation as a bilateral hearing threshold of 70 decibels (dB) or greater PTA (that is, pure-tone air-conduction average) at 500, 1000, and 2000 Hz. In infants 12 to 24 months of age, thresholds of 90 dB or greater at 1000 Hz. is considered profound hearing loss and, in children 24 months to 17 years, severe to profound bilateral hearing loss is considered to be thresholds greater than 70 dB. Moderate to profound hearing loss is defined by the Centers for Medicare and Medicaid (CMS) as, "Test scores of less than or equal to 40% correct in the best-aided listening condition on tape-recorded tests of open-set sentence cognition." Benefit from acoustic hearing aids for adults is defined as a score of 50% or greater on the Bamford-Kowal-Bench (BKB) Sentence testing at a sound intensity of 70 dB. In very young children aged 2 years and under, accurate assessment of hearing level and functional communication is difficult to confirm. However,

This Clinical UM Guideline is intended to provide assistance in interpreting Healthy Blue's standard Medicaid benefit plan. When evaluating insurance coverage for the provision of medical care, federal, state and/or contractual requirements must be referenced, since these may limit or differ from the standard benefit plan. In the event of a conflict, the federal, state and/or contractual requirements for the applicable benefit plan coverage will govern. Healthy Blue reserves the right to modify its Policies and Guidelines as necessary and in accordance with legal and contractual requirements. This Clinical UM Guideline is provided for informational purposes. It does not constitute medical advice. Healthy Blue may also use tools and criteria developed by third parties, to assist us in administering health benefits. Healthy Blue's Policies and Guidelines are intended to be used in accordance with the independent professional medical judgment of a qualified health care provider and do not constitute the practice of medicine or medical advice.

Air Conduction Hearing Aids

adequate benefit from acoustic hearing aids in children is generally demonstrated by speech, language and listening skills that are considered appropriate to the child's age, developmental stage, and cognitive ability.

According to the American Speech Language Hearing Association (ASLHA), the following classification system is commonly used to demonstrate the degree of hearing loss:

Degree of hearing loss by range in dB:

Normal – 10 to 15 dB;

Slight – 16 to 25 dB;

Mild – 26 to 40 dB;

Moderate – 41 to 55 dB;

Moderately severe – 56 to 70 dB;

Severe – 71 to 90 dB;

Profound – 91+dB (ASLHA, 2015).

The ASLHA provided the following additional information regarding hearing loss:

The configuration, or shape, of the hearing loss refers to the degree and pattern of hearing loss across frequencies (tones) as illustrated in a graph called an audiogram. For example, a hearing loss that only affects the high tones would be described as a high-frequency loss. Its configuration would show good hearing in the low tones and poor hearing in the high tones. On the other hand, if only the low frequencies were affected, the configuration would show poorer hearing for low tones and better hearing for high tones. Some hearing loss configurations are flat, indicating the same amount of hearing loss for low and high tones (ASLHA, 2015).

All types of hearing aids work by providing amplification of sound but they function in different ways. The air conduction (acoustic) hearing aid is the standard treatment for sensorineural hearing loss, mixed hearing loss and for conductive hearing loss which has been unresponsive to medical and surgical treatment. These devices are available in a variety of models which are primarily designed for external use either behind-the-ear or custom-made models for in-the-ear or in-the-ear canal. Advances in technology have introduced enhancements in functionality beyond the basic analog models, such as digital signal processing, directional microphones and devices with multiple channels and memories. These features are intended to improve performance, noise reduction and the speech of the hearing aid recipient. Despite these improvements in technology, some users continue to struggle with the audio quality of conventional hearing aids that is related to background noise and the conflicting effects on sound quality due to others speaking in close proximity to the hearing aid wearer (Ricketts, 2001).

The safety and effectiveness of conventional acoustic (air conduction) hearing aids is well established. The decision to use an acoustic (air conduction) hearing aid is best determined by the affected individual in consultation with their treating physician.

Definitions

Analog Hearing Aids: These acoustic hearing aid devices convert sound waves into electrical signals, which are amplified. Analog/adjustable hearing aids are custom built to meet the needs of each user. The aid is programmed by the manufacturer according to the specifications recommended by the audiologist.

This Clinical UM Guideline is intended to provide assistance in interpreting Healthy Blue's standard Medicaid benefit plan. When evaluating insurance coverage for the provision of medical care, federal, state and/or contractual requirements must be referenced, since these may limit or differ from the standard benefit plan. In the event of a conflict, the federal, state and/or contractual requirements for the applicable benefit plan coverage will govern. Healthy Blue reserves the right to modify its Policies and Guidelines as necessary and in accordance with legal and contractual requirements. This Clinical UM Guideline is provided for informational purposes. It does not constitute medical advice. Healthy Blue may also use tools and criteria developed by third parties, to assist us in administering health benefits. Healthy Blue's Policies and Guidelines are intended to be used in accordance with the independent professional medical judgment of a qualified health care provider and do not constitute the practice of medicine or medical advice.

Audiometry testing: A method of testing for hearing loss; two modalities utilized are pure tone audiometry and Auditory Steady State Response (ASSR). The severity of hearing loss is measured in frequencies. Pure tone audiometry utilizes measurements of pure tone hearing thresholds in a variety of settings. Hearing thresholds are defined as the lowest decibel hearing level at which responses occur in at least one-half of a series of ascending trials. ASSR is an objective test used for evaluation of hearing ability in children too young for traditional audiometric testing. Results are obtained by measuring brain activity while the person listens to tones of varying frequency (pitch) and intensity (loudness). The results obtained from ASSR testing can be used to estimate the behavioral pure-tone audiogram.

Automated Auditory Brainstem Response (AABR) test: A method of testing newborns for hearing ability; sensors are placed on his/her head to measure brain wave activity in response to sound.

Bamford-Kowal-Bench (BKB) Sentence testing: A speech perception assessment performed on children 6 years of age and older which consists of multiple lists of 16 sentences. The test may be administered in an open-set format or with a set of picture choices. The child is asked to repeat words that are understood or is directed to point to a picture of the word when heard. This test can also be administered in 4-talker babble. In this format, known as the BKB-SIN (speech in noise) test, the level of background noise increases incrementally. Key words in each sentence are marked and the number of correct words is used to calculate an average signal-to-noise ratio where a child can understand 50% of the sentences. The lower the score, the better the child performs.

Binaural Hearing Loss: A term which refers to bilateral hearing loss in both ears; these individuals can be candidates for binaural hearing aid devices (in both ears) when use of two devices helps to improve sound quality, sound localization, speech intelligibility in noisy environments and speech recognition in eligible individuals.

Conditioned Play Audiometry (CPA) test: A method of hearing test used for children aged 2 to 4 years; the child is asked to perform a simple play activity, such as placing a ring on a peg, when they hear a sound. Older children and adults may be asked to press a button or raise their hand when they hear sounds.

Conductive Hearing Loss: Refers to hearing loss due to inefficient conduction of sound through the outer ear canal to the eardrum and the tiny bones (ossicles) of the middle ear. Conductive hearing loss usually involves a reduction in sound level or the ability to hear faint sounds.

Decibel (dB): A unit of measurement indicating the loudness of sound. The intensity relates to how loud or soft a sound is. Sound scales are based on either sound pressure level (dB SPL) or hearing level (dB HL).

Digital Hearing Aids: These acoustic hearing aid devices convert sound waves into numerical codes, similar to the binary code of a computer, before amplifying them. Because the code also includes information about a sound's pitch or loudness, the aid can be specially programmed to amplify some frequencies more than others. Digital signal processing devices are digitally programmable hearing aids that utilize digitalized sound processing to convert sound waves into digital signals. These devices are self-adjusting and afford more flexibility in programming the hearing aid to align with the individual's hearing loss.

Hertz (Hz): A unit of frequency equivalent to 1 cycle per second. Frequency of pitch is measured in Hz.

This Clinical UM Guideline is intended to provide assistance in interpreting Healthy Blue's standard Medicaid benefit plan. When evaluating insurance coverage for the provision of medical care, federal, state and/or contractual requirements must be referenced, since these may limit or differ from the standard benefit plan. In the event of a conflict, the federal, state and/or contractual requirements for the applicable benefit plan coverage will govern. Healthy Blue reserves the right to modify its Policies and Guidelines as necessary and in accordance with legal and contractual requirements. This Clinical UM Guideline is provided for informational purposes. It does not constitute medical advice. Healthy Blue may also use tools and criteria developed by third parties, to assist us in administering health benefits. Healthy Blue's Policies and Guidelines are intended to be used in accordance with the independent professional medical judgment of a qualified health care provider and do not constitute the practice of medicine or medical advice.

No part of this publication may be reproduced, stored in a retrieval system or transmitted, in any form or by any means, electronic, mechanical, photocopying, or otherwise, without permission from the health plan.

Air Conduction Hearing Aids

Mixed Hearing Loss: Refers to hearing loss due to a conductive and sensorineural hearing pathology, which may be due to damage in the outer or middle ear and in the inner ear (cochlea) or auditory nerve. When this occurs, the hearing loss is referred to as a mixed hearing loss.

Otoacoustic Emissions (OAE) test: A method of testing hearing in newborns; a microphone is placed in the baby's ear through which soft clicking sounds are transmitted, and a computer then records the inner ear's response to the sounds.

Sensorineural Hearing Loss (SNHL): Refers to hearing loss due to damage to the inner ear (cochlea), or to the nerve pathways from the inner ear to the brain. In most cases, SNHL cannot be medically or surgically corrected. This is the most common type of permanent hearing loss.

Visual Reinforcement Audiometry (VRA) test: A method of testing hearing in infants over 6 months of age; a series of sounds are transmitted through earphones. The child is asked to turn toward the sound, then he/she is rewarded with an entertaining visual image.
